Talk, papers available from: http://cnls.lanl.gov/~ebn

## What is the most competitive sport?

Football

Baseball

Hockey

**Basketball** 

American Football

## What is the most competitive sport?

Can competitiveness be quantified? How can competitiveness be quantified?

# I. Modeling competitions

Pkt

80

62

# Parity of a sports league

- Teams ranked by win-loss record
- Win percentage

$$x = \frac{\text{Number of wins}}{\text{Number of games}}$$

Platz	Klub		Sp	s	U	
1	FC Red Bull Salzburg	0	36	25	5	0.763
2	SK Rapid Wien	0	36	17	11	0.625
3	SV Scholz Grödig	0	36	15	9	0.542
4	FK Austria Wien	0	36	14	11	0.542
5	SK Puntigamer Sturm Graz	0	36	13	9	0.486
6	SV Josko Ried	0	36	10	13	0.458
7	RZ Pellets WAC	0	36	11	8	0.416
8	SC Wiener Neustadt	0	36	10	9	0.403
9	FC Admira Wacker Mödling *	0	36	11	9	0.431
10	FC Wacker Innsbruck	0	36	5	14	0.333

Standard deviation in win-percentage

$$\sigma = \sqrt{\langle x^2 \rangle - \langle x \rangle^2}$$

 Cumulative distribution = Fraction of teams with winning percentage < x</li>

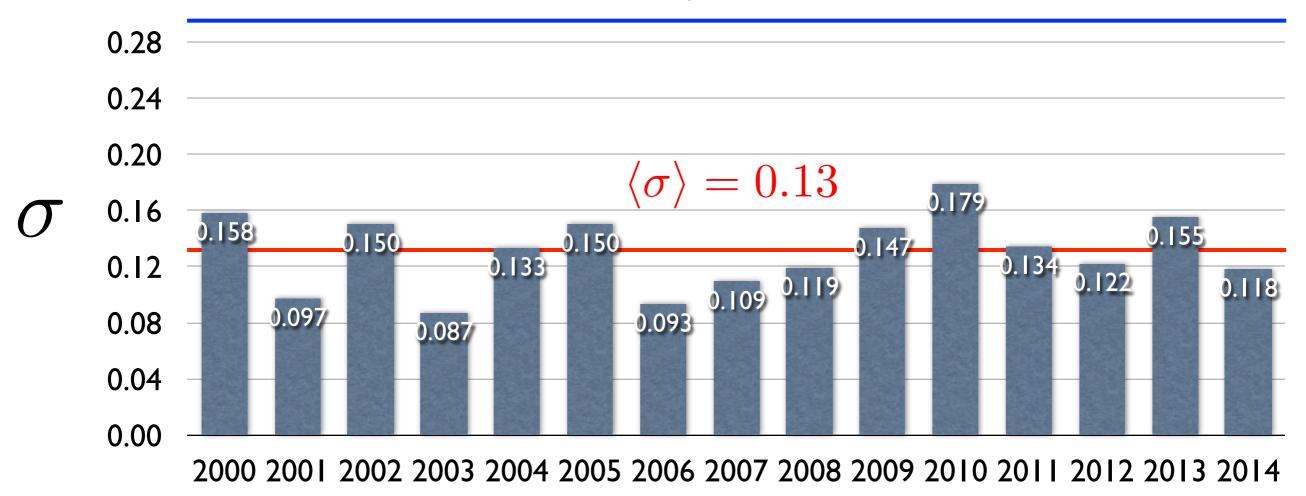

#### Austrian Bundesliga

$$\sigma = 0.13$$

# Parity by year

$$\max = \frac{1}{2\sqrt{3}} = 0.288675$$

Parity is fluctuating, without clear trend

#### Data

- 300,000 Regular season games (all games ever played)
- 5 Major sports leagues in North America & England

sport	league	full name	country	years	games
football	FA	Football Association	+	1888-2005	43,350
baseball	MLB	Major League Baseball		1901-2005	163,720
hockey	NHL	National Hockey League	*	1917-2005	39,563
basketball	NBA	National Basketball Association		1946-2005	43,254
american football	NFL	National Football League		1922-2004	11,770

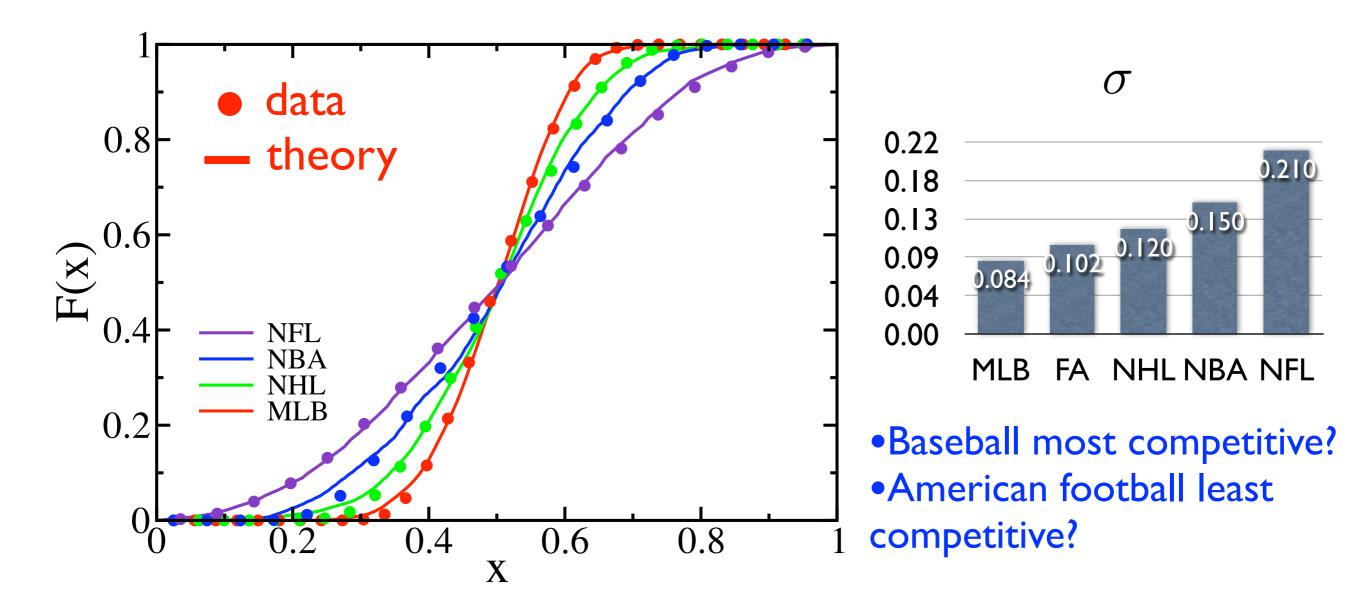

#### Standard deviation in winning percentage

Distribution of winning percentage clearly distinguishes sports

# The competition model

- Two, randomly selected, teams play
- Outcome of game depends on team record
  - Weaker team wins with probability q < 1/2  $\longrightarrow \begin{cases} q = 1/2 & \text{random} \\ q = 0 & \text{deterministic} \end{cases}$
  - Stronger team wins with probability p>1/2 p+q=1

$$(i,j) \rightarrow \begin{cases} (i+1,j) & \text{probability } p \\ (i,j+1) & \text{probability } 1-p \end{cases}$$
  $i>j$ 

- When two equal teams play, winner picked randomly
- Initially, all teams are equal (0 wins, 0 losses)
- Teams play once per unit time  $\langle x \rangle = \frac{1}{2}$

# Rate equation approach

Probability distribution functions

$$g_k$$
 = fraction of teams with  $k$  wins 
$$G_k = \sum_{j=0}^{k-1} g_j$$
 = fraction of teams with less than  $k$  wins 
$$H_k = 1 - G_{k+1} = \sum_{j=k+1}^{\infty} g_j$$

Evolution of the probability distribution

$$\frac{dg_k}{dt} = (1-q)(g_{k-1}G_{k-1} - g_kG_k) + q(g_{k-1}H_{k-1} - g_kH_k) + \frac{1}{2}\left(g_{k-1}^2 - g_k^2\right)$$
better team wins worse team wins equal teams play

Closed equations for the cumulative distribution

$$\frac{dG_k}{dt} = q(G_{k-1} - G_k) + (1/2 - q)(G_{k-1}^2 - G_k^2)$$

Boundary Conditions  $G_0 = 0$   $G_{\infty} = 1$  Initial Conditions  $G_k(t = 0) = 1$ 

#### Nonlinear Difference-Differential Equations

A kinetic view of statistical physics, Krapivsky, Redner, EB, Cambridge University Press, 2010

#### An exact solution

Stronger always wins (q=0)

$$\frac{dG_k}{dt} = G_k(G_k - G_{k-1})$$

• Transformation into a ratio

$$G_k = \frac{P_k}{P_{k+1}}$$

• Nonlinear equations reduce to linear recursion

$$\frac{dP_k}{dt} = P_{k-1}$$

EB, Krapivsky J Phys A 2012

Integrable (discrete) Burgers equation!

$$G_k = \frac{1 + t + \frac{1}{2!}t^2 + \dots + \frac{1}{k!}t^k}{1 + t + \frac{1}{2!}t^2 + \dots + \frac{1}{(k+1)!}t^{k+1}}$$

# Long-time asymptotics

Long-time limit

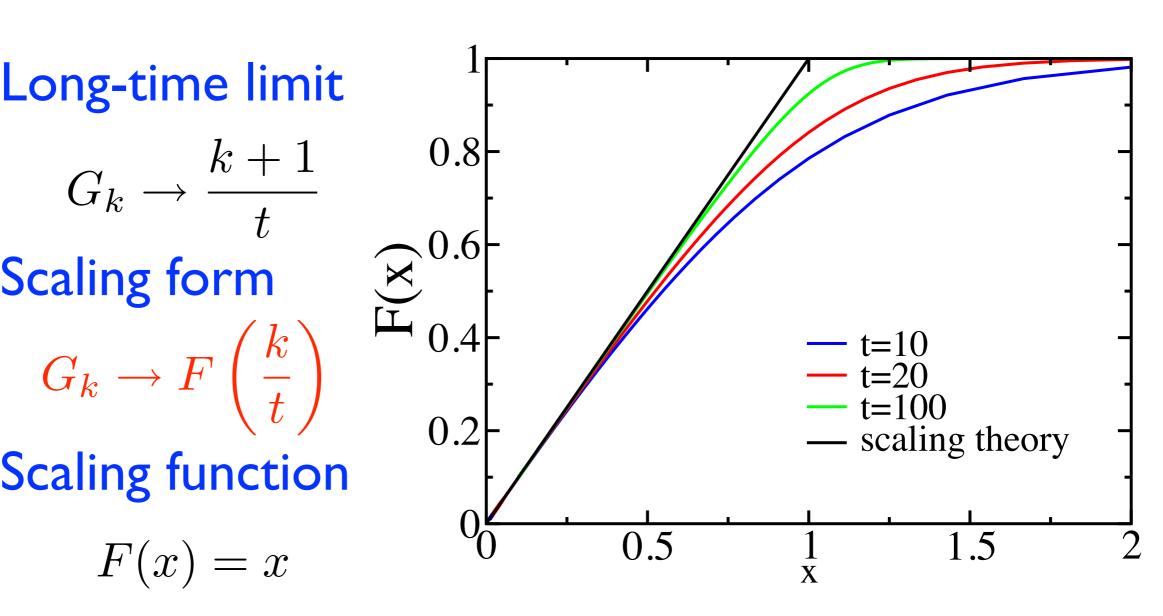

$$G_k \rightarrow \frac{k+1}{t}$$
 0.8

Scaling form

$$G_k o F\left(rac{k}{t}
ight)$$

Scaling function

$$F(x) = x$$

Seek similarity solutions Use winning percentage as scaling variable

# Scaling analysis

Rate equation

$$\frac{dG_k}{dt} = q(G_{k-1} - G_k) + (1/2 - q)(G_{k-1}^2 - G_k^2)$$

• Treat number of wins as continuous  $G_{k+1} - G_k \rightarrow \frac{\partial G}{\partial k}$ 

Inviscid Burgers equation 
$$\frac{\partial v}{\partial t} + v \frac{\partial v}{\partial x} = 0 \qquad \frac{\partial G}{\partial t} + \left[ q + (1 - 2q)G \right] \frac{\partial G}{\partial k} = 0$$

Stationary distribution of winning percentage

$$G_k(t) \to F(x)$$
  $x = \frac{k}{t}$ 

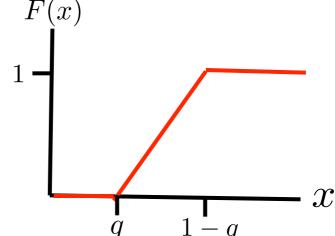

Scaling equation

$$[(x-q) - (1-2q)F(x)] \frac{dF}{dx} = 0$$

# Scaling solution

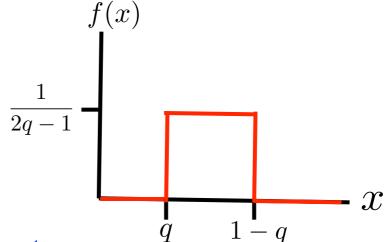

Stationary distribution of winning percentage

$$F(x) = \begin{cases} 0 & 0 < x < q \\ \frac{x - q}{1 - 2q} & q < x < 1 - q \\ 1 & 1 - q < x. \end{cases}$$

Distribution of winning percentage is uniform

$$f(x) = F'(x) = \begin{cases} 0 & 0 < x < q \\ \frac{1}{1 - 2q} & q < x < 1 - q \\ 0 & 1 - q < x. \end{cases} \xrightarrow{f(x)}$$

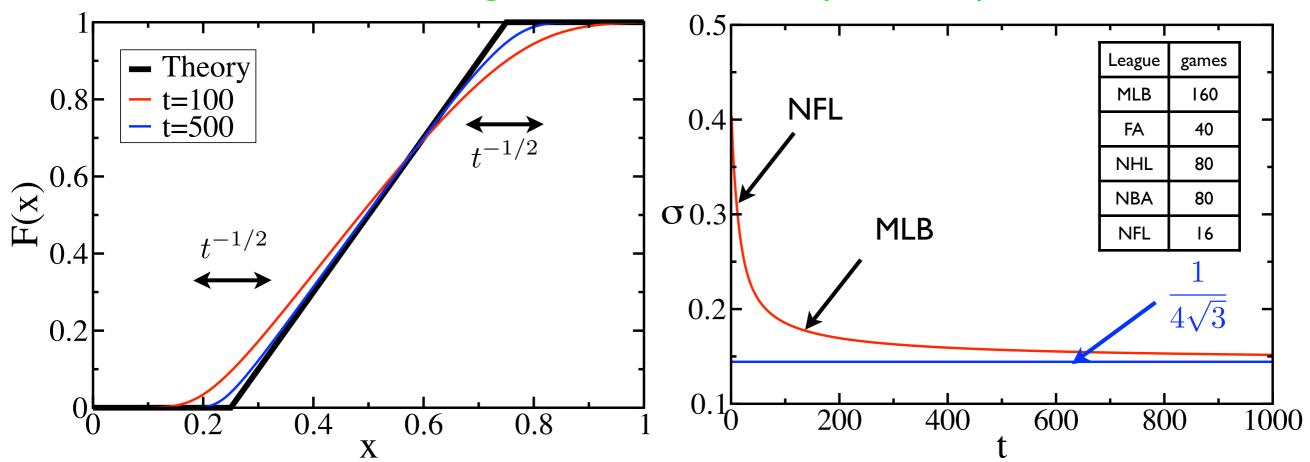

Variance in winning percentage

$$\sigma = \frac{1/2 - q}{\sqrt{3}}$$
  $\longrightarrow \begin{cases} q = 1/2 & \text{perfect parity} \\ q = 0 & \text{maximum disparity} \end{cases}$ 

# Approach to scaling

Numerical integration of the rate equations, q=1/4

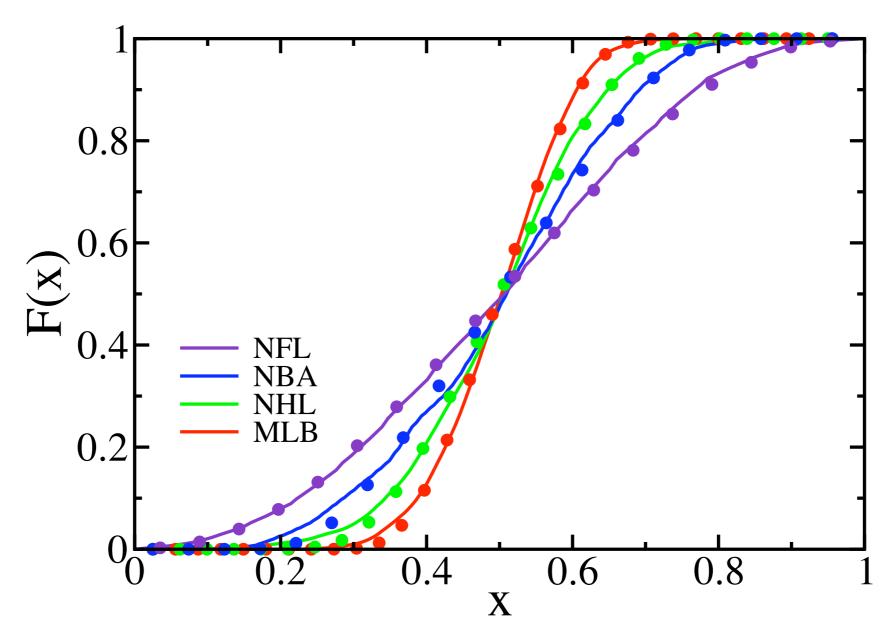

- Winning percentage distribution approaches scaling solution
- Correction to scaling is very large for realistic number of games
- Large variance may be due to small number of games

$$\sigma(t) = \frac{1/2 - q}{\sqrt{3}} (+f(t)) \leftarrow \text{Large!}$$

Variance inadequate to characterize competitiveness!

### The distribution of win percentage

- •Treat q as a fitting parameter, time=number of games
- •Allows to estimate q<sub>model</sub> for different leagues

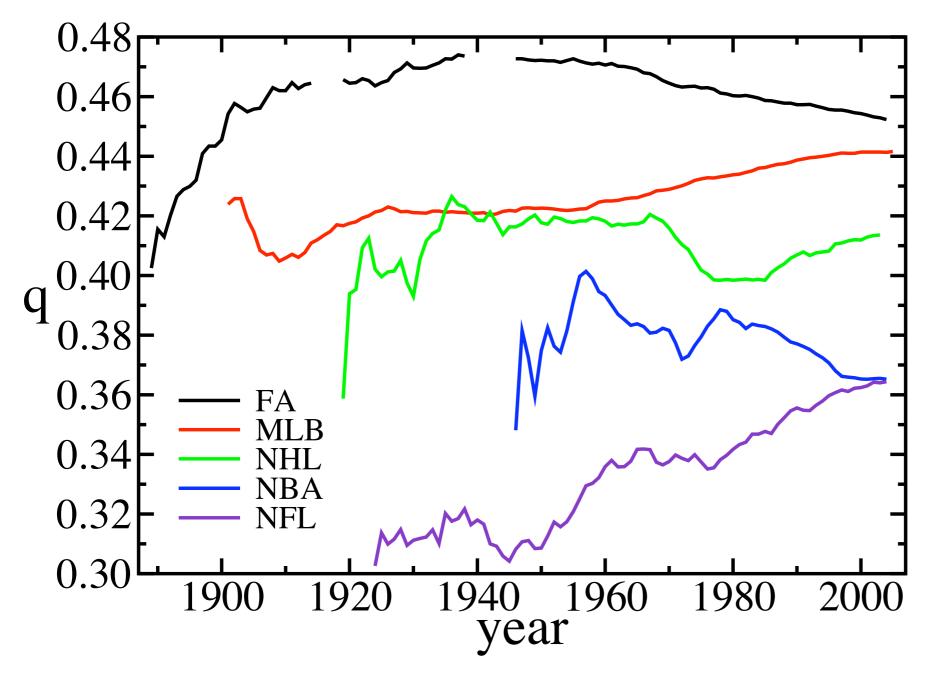

# The upset frequency

Upset frequency as a measure of predictability

$$q = \frac{\text{Number of upsets}}{\text{Number of games}}$$

- Addresses the variability in the number of games
- Measure directly from game-by-game results
  - Ties: count as 1/2 of an upset (small effect)
  - Ignore games by teams with equal records
  - Ignore games by teams with no record

# The upset frequency

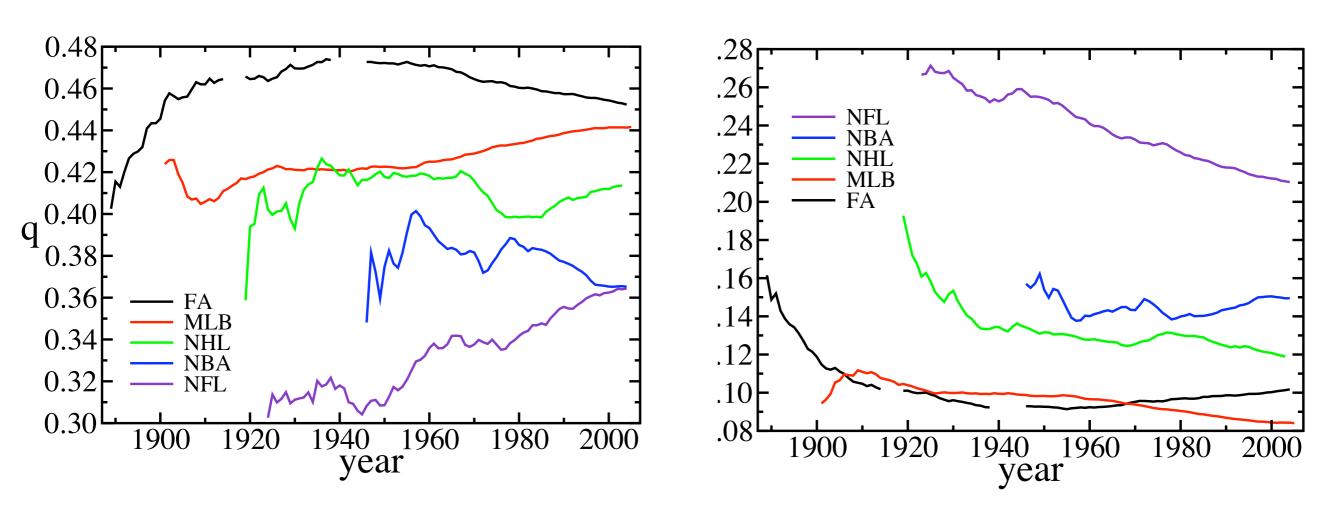

League	q	q
FA	0.452	0.459
MLB	0.441	0.413
NHL	0.414	0.383
NBA	0.365	0.316
NFL	0.364	0.309
ABL	???	0.392

q differentiates the different sport leagues!

football, baseball most competitive basketball, american football least competitive

#### Evolution with time

- •Parity, predictability mirror each other  $\sigma = \frac{1/2 q}{\sqrt{3}}$
- American football, baseball increasing competitiveness
- •Soccer decreasing competitiveness (past 60 years)

#### I. Discussion

- Model limitation: it does not incorporate
  - Game location: home field advantage
  - Game score
  - Upset frequency dependent on relative team strength
  - Unbalanced schedule
- Model advantages:
  - Simple, involves only I parameter
  - Enables quantitative analysis

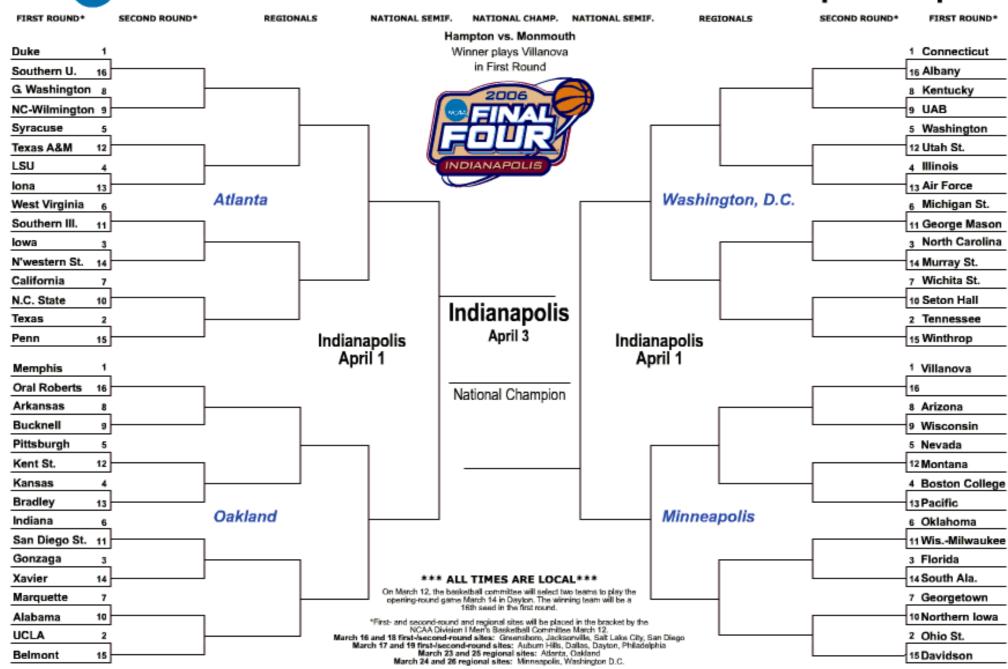

## 1. Conclusions

- Parity characterized by variance in winning percentage
  - Parity measure requires standings data
  - Parity measure depends on season length
- Predictability characterized by upset frequency
  - Predictability measure requires game results data
  - Predictability measure independent of season length
- Two-team competition model allows quantitative modeling of sports competitions

# 2. Tournaments(post-season)

## Single-elimination Tournaments

#### 🗫 2006 NCAA Division I Men's Basketball Championship

® 2005 National Collegiste Afhietic Association. No commercial use without the NCAA's written permission. The NCAA opposes all sports wagering. This bracket should not be used for sweepstakes, contests, office pools or other gambling activities.

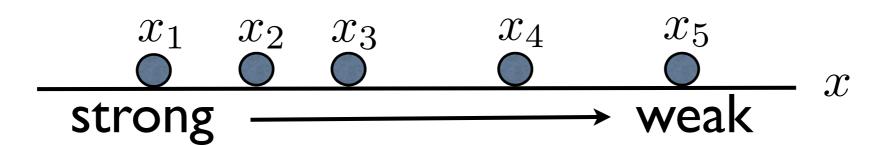

#### Binary Tree Structure

## The competition model

Two teams play, loser is eliminated

$$N \to N/2 \to N/4 \to \cdots \to 1$$

Teams have inherent strength (or fitness) x

- Outcome of game depends on team strength
  - Weaker team wins with probability q<1/2</li>
  - Stronger team wins with probability I-q>1/2

$$(x_1, x_2) \rightarrow \begin{cases} x_1 & \text{probability } 1 - q \\ x_2 & \text{probability } q \end{cases} \qquad x_1 < x_2$$

### Recursive approach

Number of teams

$$N = 2^k = 1, 2, 4, 8, \dots$$

- $G_N(x)$  = Cumulative probability distribution function for teams with fitness less than x to win an N-team tournament
- Closed equations for the cumulative distribution

$$G_{2N}(x) = 2p G_N(x) + (1 - 2p) [G_N(x)]^2$$

Nonlinear Recursion Equation

# Scaling properties

I. Scale of Winner

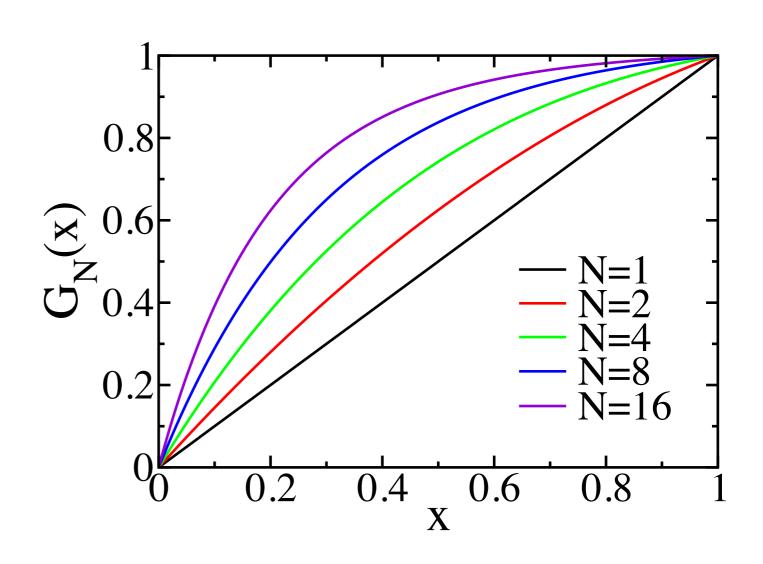

$$x_* \sim N^{-\ln 2p/\ln 2}$$

2. Scaling Function

$$G_N(x) \to \Psi(x/x_*)$$

3. Algebraic Tail

$$1 - \Psi(z) \sim z^{\ln 2p / \ln 2q}$$

- 1. Large tournaments produce strong winners
- 3. High probability for an upset

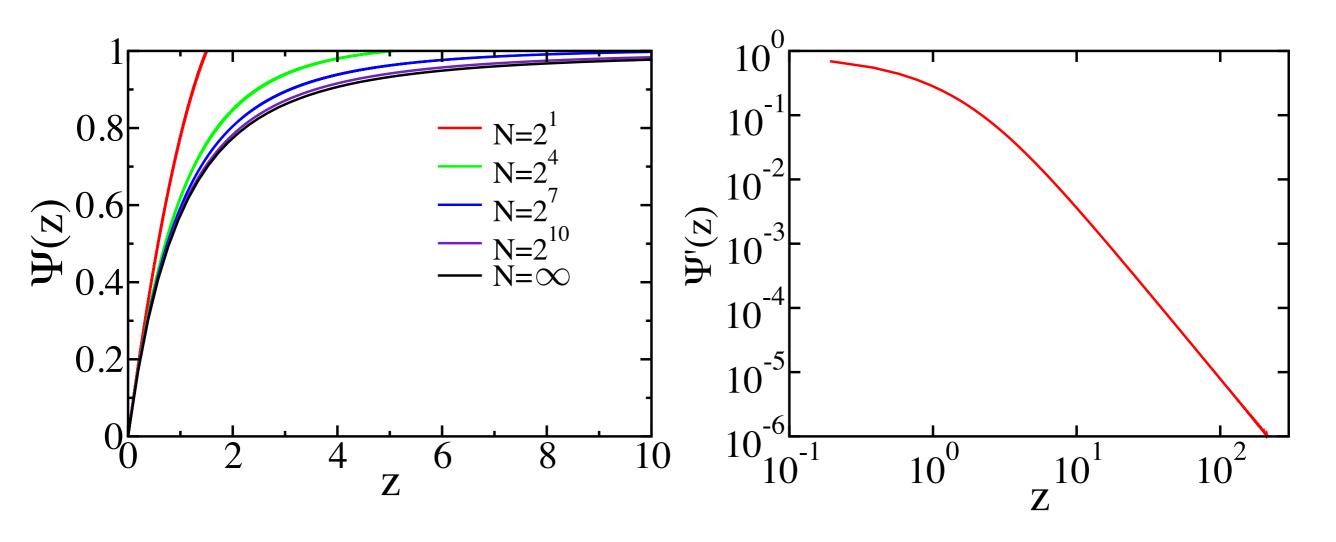

# The scaling function

#### Universal shape

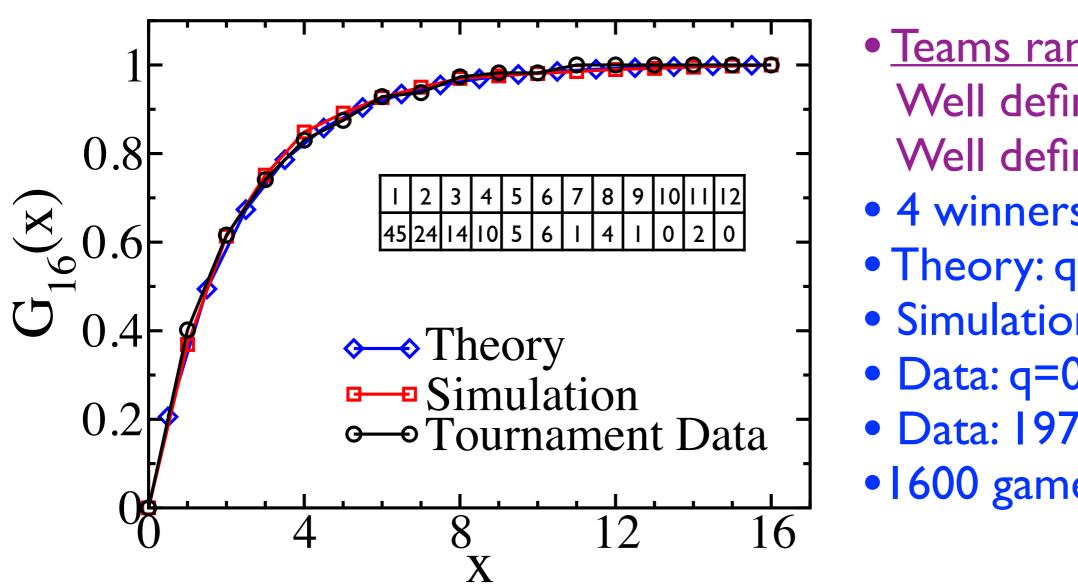

$$\Psi(2pz) = 2p\Psi(z) + (1 - 2p)\Psi^{2}(z)$$

#### Broad tail

$$\Psi'(z) \sim z^{\ln 2p/\ln 2q - 1}$$

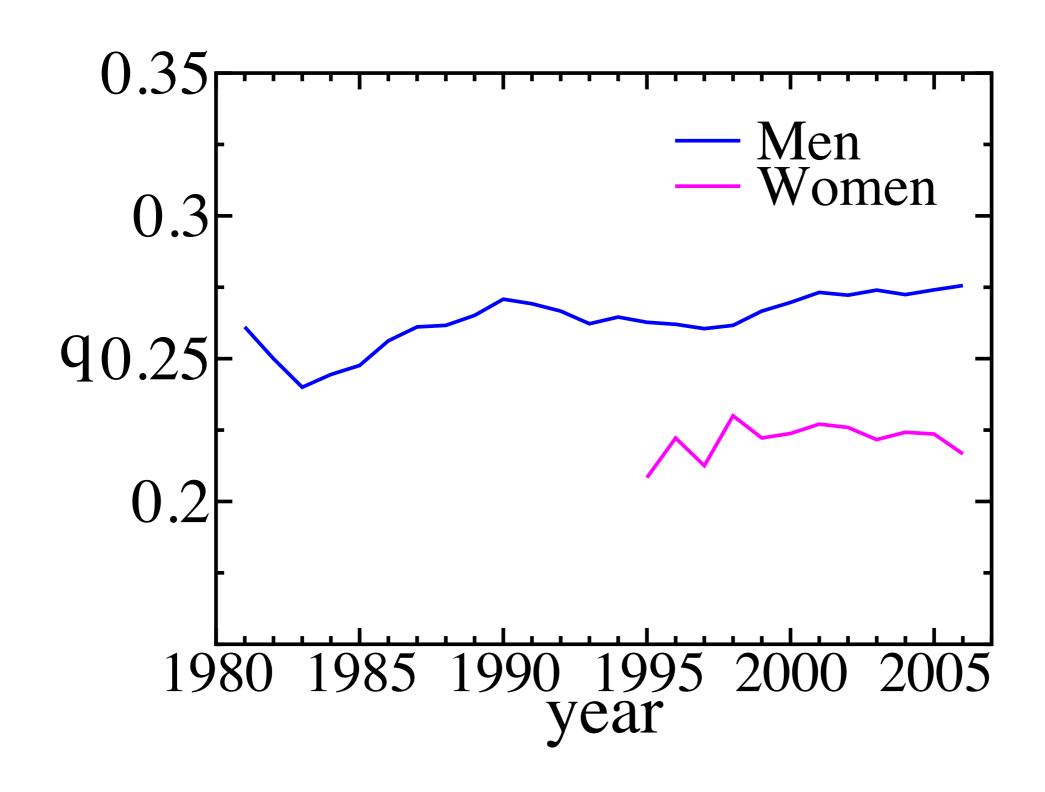

# College Basketball

- Teams ranked 1-16 Well defined favorite Well defined underdog
- 4 winners each year
- Theory: q=0.18
- Simulation: q=0.22
- Data: q=0.27
- Data: 1978-2006
- 1600 games

2008: all four top seed advance; I in 150 chance!

# Evolution, Men vs Women

### 2. Conclusions

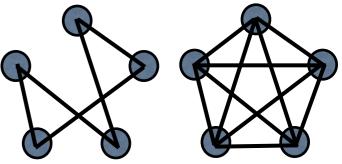

- Strong teams fare better in large tournaments
- Tournaments can produce major upsets
- Distribution of winner relates parity with predictability
- Tournaments are efficient but not fair

# 3. Leagues (regular season)

# League champions

- N teams with fixed ranking
- In each game, favorite and underdog are well defined
- Favorite wins with probability p>1/2 p+q=1 Underdog wins with probability q<1/2
- Each team plays t games against random opponents
  - Regular random graph

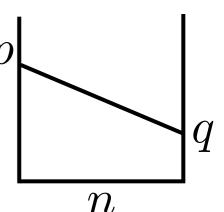

How many games are needed for best team to win?

# Random walk approach

I —

• Probability team ranked n wins a game

$$P_n = p \frac{n-1}{N-1} + q \frac{N-n}{N-1}$$

•

Number of wins performs a biased random walk

$$w_n = P_n t \pm \sqrt{D_n t}$$

•

• Team n can finish first at early times as long as

$$(2p-1)\frac{n}{N}t \sim \sqrt{t}$$

N —

Rank of champion as function of N and t

$$n_* \sim \frac{N}{\sqrt{t}}$$

# Length of season

For best team to finish first

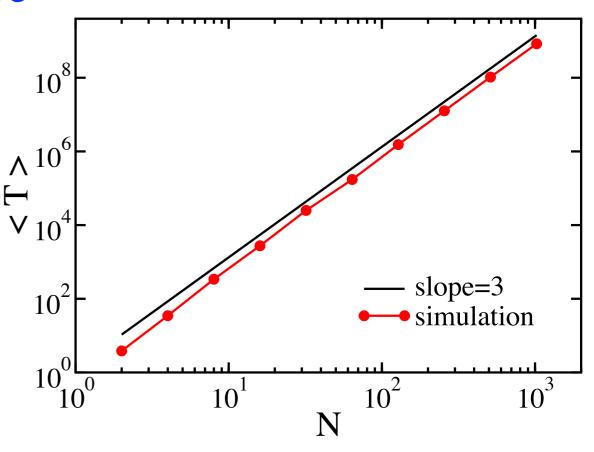

$$1 \sim \frac{N}{\sqrt{t}}$$

• Each team must play

$$t \sim N^2$$

Total number of games

$$T \sim N^3$$

- 1. Normal leagues are too short
- 2. Normal leagues: rank of winner  $\sim \sqrt{N}$
- 3. League champions are a transient!

#### Distribution of outcomes

Scaling distribution for the rank of champion

$$Q_n(t) \sim \frac{1}{n_*} \psi\left(\frac{n}{n_*}\right) \qquad \qquad n_* \sim \frac{N}{\sqrt{t}}$$

Probability worse team wins decays exponentially

$$Q_N(t) \sim \exp(-\text{const} \times t)$$

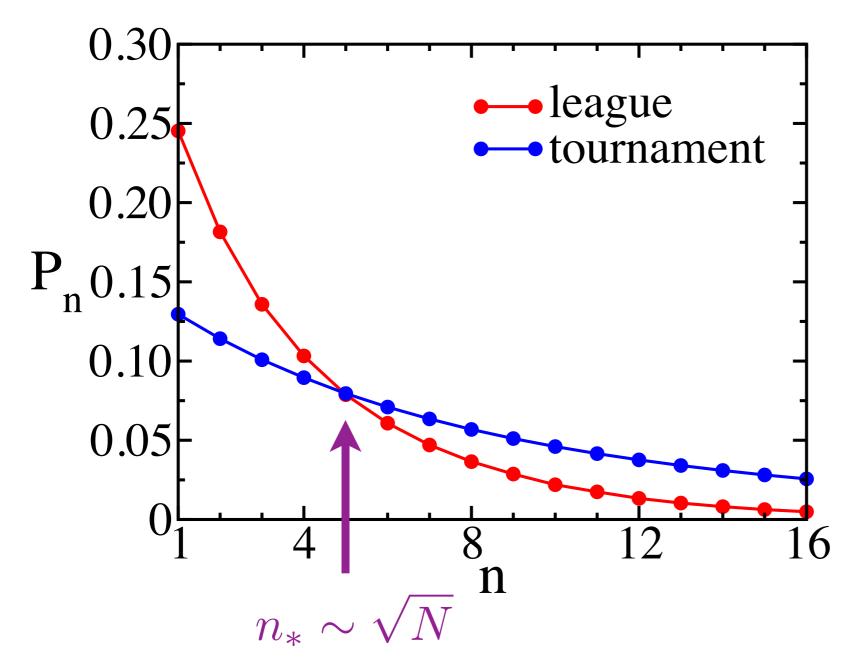

• Gaussian tail because  $\psi\left(t^{1/2}\right)\sim \exp(-t)$   $\psi(z)\sim \exp\left(-\cos t\times z^2\right)$ 

• Normal league: Prob. (weakest team wins)  $\sim \exp(-N)$ 

Leagues are fair: upset champions extremely unlikely

### Leagues versus Tournaments

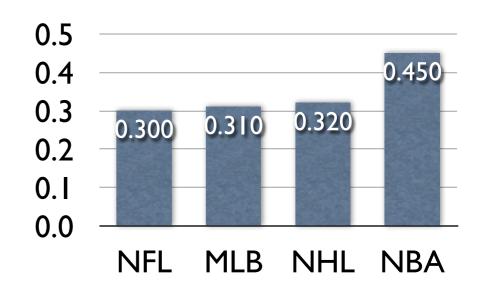

n	league	tourna ment
I	24.5	12.9
2	18.2	11.4
3	13.6	10.1
4	10.3	8.9
5	7.9	7.9
6	6. l	7.1
7	4.7	6.3
8	3.7	5.7
9	2.9	5.1
10	2.2	4.6
П	1.7	4.2
12	1.3	3.8
13	I	3.4
14	0.81	3.1
15	0.63	2.8
16	0.49	2.6

# What is the likelihood the best team has best record?

league	season	games	likelihood
NFL	short	predictable	30%
MLB*	long	random	31%
NHL	moderate	moderate	32%
NBA	moderate	predictable	45%

\*90% likelihood requires 15000 games/team!!!

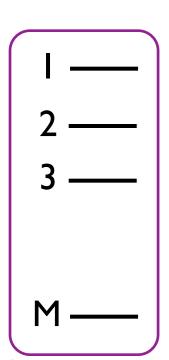

# Interplay between length of season and predictability of games

### 3. Conclusions

- Leagues are fair but inefficient
- Leagues do not produce major upsets

# 4. Ranking Algorithm

# One preliminary round

- Preliminary round
  - lacksquare Teams play a small number of games  $T \sim N \, t$
  - Top M teams advance to championship round  $\,M\sim N^{lpha}$
  - Bottom N-M teams eliminated
  - Best team must finish no worse than M place  $~t \sim \frac{N^2}{M^2}$
- Championship round: plenty of games  $T \sim M^3$
- Total number of games

$$T \sim N^{3-2\alpha} + N^{3\alpha}$$

Minimal when

$$M \sim N^{3/5} \qquad T \sim N^{9/5}$$

## Two preliminary rounds

Two stage elimination

$$N \to N^{\alpha_2} \to N^{\alpha_2 \alpha_1} \to 1$$

Second round

$$T_2 \sim N^{3-2\alpha_2} + N^{\alpha_2(3-2\alpha_1)} + N^{3\alpha_1\alpha_2}$$

Minimize number of games

$$3 - 2\alpha_2 = \alpha_2(3 - 2\alpha_1) \qquad \longrightarrow \qquad \alpha_2 = \frac{15}{19}$$

Further improvement in efficiency

$$T \sim N^{27/19}$$

## Multiple preliminary rounds

Each additional round further reduces T

$$T_k \sim N^{\gamma_k}$$
  $\gamma_k = \frac{1}{1 - (2/3)^{k+1}}$ 

Gradual elimination

$$\gamma_k = 3, \frac{9}{5}, \frac{27}{19}, \frac{81}{65}, \cdots$$

$$N \to N^{\frac{57}{65}} \to N^{\frac{57}{65}\frac{15}{19}} \to N^{\frac{57}{65}\frac{15}{19}\frac{3}{5}} \to 1$$

Teams play a small number of games initially

Optimal linear scaling achieved using many rounds

$$T_{\infty} \sim N$$
  $M_{\infty} \sim N^{1/3}$  optimal size of playoffs!

Preliminary elimination is very efficient!

### 4. Conclusions

- Gradual elimination is fair and efficient
- Preliminary rounds reduce the number of games
- In preliminary round, teams play a small number of games and almost all teams advance to next round

# 5. Social Dynamics

### Competition and social dynamics

- Teams are agents
- Number of wins represents fitness or wealth
- Agents advance by competing against each other
- Competition is a mechanism for social differentiation

### The social diversity model

Agents advance by competition

$$(i,j) \rightarrow \begin{cases} (i+1,j) & \text{probability } p \\ (i,j+1) & \text{probability } 1-p \end{cases}$$
  $i>j$ 

Agent decline due to inactivity

$$k \to k-1$$
 with rate  $r$ 

Rate equations

$$\frac{dG_k}{dt} = r(G_{k+1} - G_k) + pG_{k-1}(G_{k-1} - G_k) + (1-p)(1-G_k)(G_{k-1} - G_k) - \frac{1}{2}(G_k - G_{k-1})^2$$

Scaling equations

$$[(p+r-1+x)-(2p-1)F(x)]\frac{dF'}{dx}=0$$

#### Organization into Social Structure

1/2

#### I. Middle class

Agents advance at different rates

#### 2. Middle+lower class

• Some agents advance at different rates

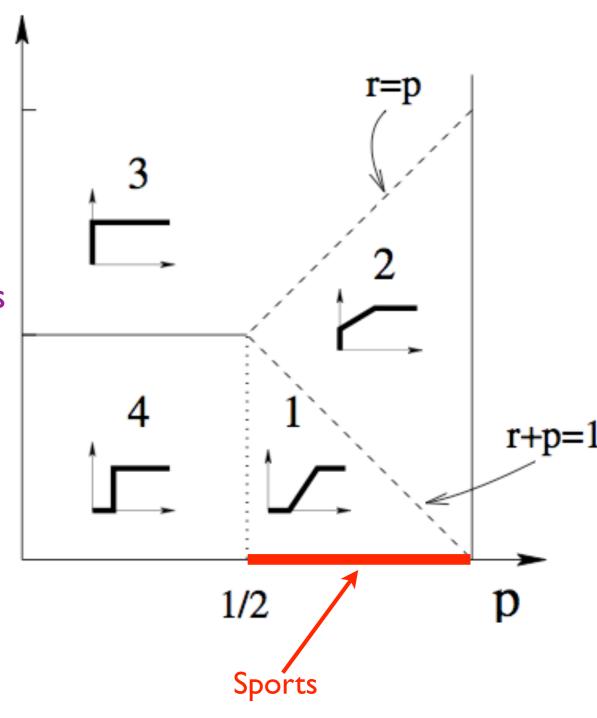

• Some agents do not advance

#### 3. Lower class

Agents do not advance

#### 4. Egalitarian class

All agents advance at equal rates

# Concluding remarks

- Mathematical modeling of competitions sensible
- Minimalist models are a starting point
- Randomness a crucial ingredient
- Validation against data is necessary for predictive modeling
